# How Real Teams Are Powering AI Security with the Contrast MCP Server

By Jacob Mages-Haskins, Principal Software Engineer

October 30, 2025

When we introduced the Contrast Model-Context Protocol (MCP) Server a few months ago (read [Supercharge your vulnerability remediation with Contrast MCP](#)), the promise was clear: to give AI agents access to the rich security context within the Contrast Graph, which is a real-time application security data model that continuously maps, updates and correlates security insights across applications, APIs and infrastructure.

assisted secure development.

As a quick refresher, the MCP Server is the crucial bridge that gives your Large Language Model (LLM) agent the tools it needs to securely interact with the Contrast Security API and access the data in your Contrast Graph.

In this post, we'll move past the introduction to highlight real customer use cases, and then provide the full quick-start guide to setting up the Contrast MCP Server in your own environment.

## The Contrast MCP Server in Action: Driving Real-World Outcomes

Here are a few high-value use cases our early adopters are implementing:

### Use Case 1: AI-Driven Vulnerability Remediation

This is the most impactful use case. When a vulnerability is found, the AI agent doesn't just see a line of insecure code. Because of the MCP Server, the agent can access the full security context from Contrast, including:

The environment and application details.

The AI agent uses this complete picture, not just the code snippet, to generate a precise, context-aware fix or a secure code refactor, drastically reducing the time required for a human to step in and improving the accuracy of the AI coding assistant.

Here are example prompts that you can use with your AI coding assistant:

What are the most critical vulnerabilities in this application that Contrast knows about?

In Contrast, which routes for this application have critical CVEs?

Fix the most important vulnerability identified by Contrast.

## Use Case 2: Automating Security Posture Reports

Instead of manually pulling data from different dashboards, an AI agent, connected via the MCP Server, can quickly query the

Identifying the most critical, reachable vulnerabilities.

Aggregating security metrics across multiple applications.

Translating technical findings into business risk (e.g., building an HTML report with graphs and high-level summaries for a CISO presentation).

This capability automates security intelligence and reporting, freeing up security teams to focus on mitigation.

Example report-building prompt:

As a CISO, I want to present the Contrast data for this project to business people. Build me an HTML report that uses nice graphs and pictures to display a simple, but comprehensive picture of the security position of this application, what would happen if this were running on the public internet, and what are the chances and timeframe of exposure, and what could be lost.

It is imperative to note here, though, that exposing your Contrast vulnerability data via an MCP Server to an LLM that trains on your data is dangerous. You must use an enterprise-grade, "sandboxed" LLM that guarantees your data is not used for further training. Examples include models targeted to the enterprise market, like those available through AWS Bedrock or those used for GitHub Copilot and Claude Code.

It is your responsibility to thoroughly research and validate your specific LLM provider's data usage and security policy before deploying the Contrast MCP Server.

## Setting up Contrast MCP Locally

The first step is setting up the Contrast MCP Server on your local machine. Refer to the documentation at <https://github.com/Contrast-Security-OSS/mcp-contrast> to find the most appropriate setup method for your IDE or project.

### Example: GitHub Copilot in Visual Studio Code

Here is a concrete example for a popular setup. For all others, check the official documentation first!

Install the Contrast MCP Server in Visual Studio Code with Docker from this [installation link](#).

Download the latest JAR file (requires Java 17+): <https://github.com/Contrast-Security-OSS/mcp-contrast/releases/latest>

## 2. Configure VS Code

Create a new config file at the root of your project: .vscode/mcp.json

This file tells your setup how to run the Java-based MCP Server and provides the necessary details to connect to the Contrast Security API (like your API keys and host name). Most of the connection details can be found on the User Settings page of the Contrast Security UI.

Last, Enable the Tool in Copilot:

Open the Copilot chat pane.

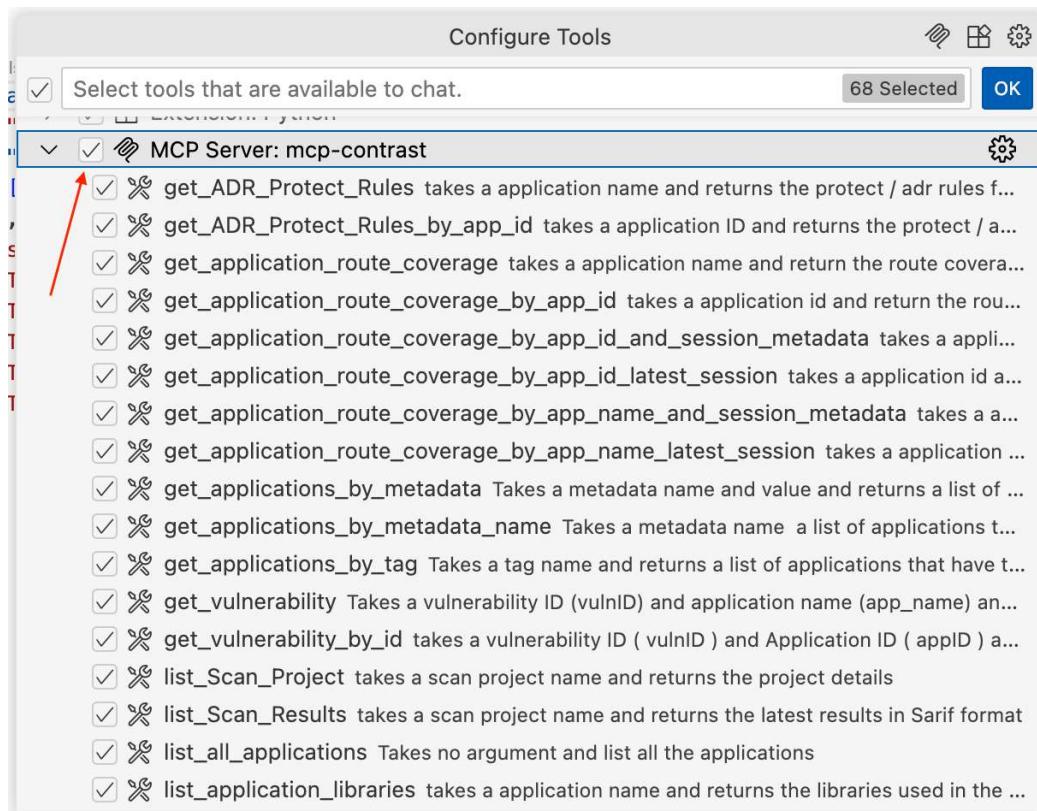

Put Copilot into "Agent" mode.

Click the tools icon.

In the tool dialog window, enable the Contrast MCP Server tools.

The screenshot shows the Contrast MCP Server interface. At the top, there's a navigation bar with links for Products, Solutions, Partner, Customers, Company, and Resources. Below the navigation bar is a search bar with the placeholder text "Add context (#), extensions (@), commands ()". A red arrow points from the text "Put Copilot in Agent mode and click the tools icon" to the dropdown menu next to the search bar, which is set to "Agent" and displays "Claude Sonnet 4". To the right of the search bar are two icons: a wrench and a gear.

Put Copilot in Agent mode and click the tools icon

Enable the Contrast MCP Server in the tools dialog

## Power of the Contrast Graph + AI

Now that the Contrast MCP Server is installed and enabled in your environment, your AI agents can finally use the data in the
